

2nd International Olympiad on Astronomy and Astrophysics

# The 2nd International Olympiad on Astronomy and Astrophysics Bandung, Indonesia Saturday, 23 August 2008 Theoretical Competition

#### Please read this carefully:

- 1. Every student receives problem sheets in English and/or in native language, an answer book and a scratch book.
- 2. The time available is 5 hours for the theoretical competition. There are fifteen short questions (Theoretical Part 1), and three long questions (Theoretical Part 2).
- 3. Use only Black or dark blue pen
- 4. Use only the front side of answer sheets. Write only inside the boxed area.
- 5. Begin answering each question on a separate sheet.
- 6. Numerical results should be written with as many digits as are appropriate.
- 7. Write on the blank **answer sheets** whatever you consider is required for the solution of each question. Please express your answer primarily in term of equations, numbers, figures, and plots. If necessary provide your answers with concise text. <u>Full credit will</u> <u>be given to correct answer with detailed steps for each question.</u> Underline your final result.
- 8. Fill in the boxes at the top of each sheet of paper with your country code and your student code.
- 9. At the end of the exam place the books inside the envelope and leave everything on your desk.

# 2<sup>nd</sup> IOAA

	N. N	
Quantity	Value	
Astronomical unit (AU)	149 597 870 691 m	
Light year (ly)	$9.4605 \times 10^{15} \text{ m} = 63,240 \text{ AU}$	
Parsec (pc)	$3.0860 \times 10^{16} \text{ m} = 206,265 \text{ AU}$	
Sidereal year	365.2564 days	
Tropical year	365.2422 days	
Gregorian year	365.2425 days	
Sidereal month	27.3217 days	
Synodic month	29.5306 days	
Mean sidereal day	23 <sup>h</sup> 56 <sup>m</sup> 4 <sup>s</sup> .091 of mean solar time	
Mean solar day	24 <sup>h</sup> 3 <sup>m</sup> 56 <sup>s</sup> .555 of sidereal time	
Mean distance, Earth to Moon	384 399 000 m	
Earth mass (M⊕)	$5.9736 \times 10^{24} \text{ kg}$	
Earth mean radius	6 371 000 m	
Earth mean velocity in orbit	29 783 m/s	
Moon mass $(M_{y})$	$7.3490 \times 10^{22} \text{ kg}$	
Moon mean radius	1 738 000 m	
Sun mass $(M_{\odot})$	$1.9891 \times 10^{30} \text{ kg}$	
Sun radius $(R_{\odot})$	$6.96 \times 10^8 \mathrm{m}$	
Sun luminosity $(L_{\odot})$	$3.96 \times 10^{26} \mathrm{J \ s^{-1}}$	
Sun effective temperature $(T_{eff_{\odot}})$	5 800 °K	
Sun apparent magnitude $(m_{\odot})$	-26.8	
Sun absolute magnitude $(M_{\odot})$	4.82	
Sun absolute bolometric magnitude $(M_{bol_{\odot}})$	4.72	
Speed of light ( <i>c</i> )	$2.9979 \times 10^8$ m/s	
Gravitational constant (G)	$6.6726 \times 10^{-11} \text{ N m}^2 \text{ kg}^{-2}$	
Boltzmann constant (k)	$1.3807 \times 10^{-23} \text{ J K}^{-1}$	
Stefan-Boltzmann constant ( $\sigma$ )	$5.6705 \times 10^{-8} \text{ J s}^{-1} \text{ m}^{-2} \text{ K}^{-4}$	
Planck constant ( <i>h</i> )	$6.6261 \times 10^{-34} \text{ J s}$	
Electron charge ( <i>e</i> )	$1.602 \times 10^{-19} \text{ C} = 4.803 \times 10^{-10} \text{ esu}$	
Electron mass $(m_e)$	$5.48579903 \times 10^{-4}$ amu = $9.11 \times 10^{-31}$ kg	
Proton mass $(m_p)$	$1.00727647 \text{ amu} = 1.67268 \times 10^{-27} \text{ kg}$	

Neutron mass $(m_n)$	$1.008664904 \text{ amu} = 1.67499 \times 10^{-27} \text{ kg}$
Deuterium nucleus mass $(m_d)$	$2.013553214 \text{ amu} = 3.34371 \times 10^{-27} \text{ kg}$
Hydrogen mass	$1.00794 \text{ amu} = 1.67379 \times 10^{-27} \text{ kg}$
Helium mass	$4.002603 \text{ amu} = 1.646723 \times 10^{-27} \text{ kg}$

Conversion table		
1 Å	$0.1 \text{ nm} = 10^{-10} \text{ m}$	
1 barn	$10^{-28} \text{ m}^2$	
1 G	10 <sup>-4</sup> T	
1 erg	$10^{-7}$ J = 1 dyne cm	
1 esu	$3.3356 \times 10^{-10} \text{ C}$	
1 amu (atomic mass unit)	$1.6606 \times 10^{-27} \mathrm{kg}$	
1 atm (atmosphere)	101,325 Pa = 1.01325 bar	
1 dyne	10 <sup>-5</sup> N	

## **THEORETICAL PART 1**

#### (300 points for 15 Theoretical Part-1 questions, 20 points for each question)

Show your method of solution step by step in the answer sheets completely as your final answer. The scratch sheet is to be used for your personal calculation and will not be marked. Partial credits will be given for answers without showing method of solution.

- Two persons, on the equator of the Earth separated by nearly 180° in longitude, observe the Moon's position with respect to the background star field at the same time. If the declination of the Moon is zero, sketch the situation and calculate the difference in apparent right ascension seen by those two persons.
- 2. On April 2, 2008 a telescope (10 cm diameter, f/10) at the Bosscha Observatory was used to observe the Sun and found an active region 0987 (based on the NOAA number) at 8° South and 40° West from the center of the solar disk. The region was recorded with a CCD SBIG ST-8 Camera (1600 × 1200 pixels, (9 µm × 9 µm)/ pixel) and its size was 5 × 4 pixels. According to the Astronomical Almanac, the solar diameter is 32'. How large is the corrected area of the active region in unit of millionth of solar hemisphere (msh)?
- 3. A full moon occurred on June 19, 2008 at  $00^{h} 30^{m}$  West Indonesian Time (local civil time for western part of Indonesia with meridian of  $105^{\circ}$  E). Calculate the minimum and maximum possible values of duration of the Moon above the horizon for observers at Bosscha Observatory (longitude:  $107^{\circ} 35' 00''.0$  E, latitude:  $6^{\circ} 49' 00''.0$  S, Elevation: 1300.0 m). Time zone = UT + $7^{h} 00^{m}$ .
- 4. Suppose a star has a mass of 20 𝔐<sub>☉</sub>. If 20% of the star's mass is now in the form of helium, calculate the helium-burning lifetime of this star. Assume that the luminosity of the star is 100 L<sub>☉</sub>, in which 30% is contributed by helium burning. The carbon mass, <sup>12</sup>C, is 12.000000 amu. Helium burning to Carbon: 3 <sup>4</sup>He → <sup>12</sup>C + γ.
- 5. The average temperature of the Cosmic Microwave Background (CMB) is currently T = 2.73 K, and it yields the origin of CMB to be at redshift  $z_{CMB} = 1100$ . The current densities of the Dark Energy, Dark Matter, and Normal Matter components of the Universe as a whole are  $\rho_{DE} = 7.1 \times 10^{-30}$  g/cm<sup>3</sup>,  $\rho_{DM} = 2.4 \times 10^{-30}$  g/cm<sup>3</sup>, and

 $\rho_{\rm NM} = 0.5 \times 10^{-30} \text{ g/cm}^3$ , respectively. What is the ratio between the density of Dark Matter to the density of Dark Energy at the time CMB was emitted, if we assume that the dark energy is vacuum energy?

- 6. Radio wavelength observations of gas cloud swirling around a black hole in the center of our galaxy show that radiation from the hydrogen spin-flip transition (rest frequency = 1420.41 MHz) is detected at a frequency of 1421.23 MHz. If this gas cloud is located at a distance of 0.2 pc from the black hole and is orbiting in a circle, determine the speed of this cloud and whether it's moving toward or away from us and calculate the mass of the black hole.
- 7. A main sequence star at a distance 20 pc is barely visible through a certain space-based telescope which can record all wavelengths. The star will eventually move up along the giant branch, during which time its temperature drops by a factor of 3 and its radius increases 100 times. What is the new maximum distance at which the star can still be (barely) visible using the same telescope?
- 8. Gravitational forces of the Sun and the Moon lead to the raising and lowering of sea water surfaces. Let  $\varphi$  be the difference in longitude between points A and B, where both points are at the equator and A is on the sea surface. Derive the horizontal acceleration of sea water at position A due to Moon's gravitational force at the time when the Moon is above point B according to observers on the Earth (express it in  $\varphi$ , the radius **R** of Earth, and the Earth-Moon distance r).
- 9. The radiation incoming to the Earth from the Sun must penetrate the Earth's atmosphere before reaching the earth surface. The Earth also releases radiation to its environment and this radiation must penetrate the Earth's atmosphere before going out to the outer space. In general, the transmittance  $(t_1)$  of the Sun radiation during its penetration through the Earth's atmosphere is higher than that of the radiation from the Earth  $(t_2)$ . Let  $T_{\text{eff}_{\odot}}$  be the effective temperature of the Sun,  $R_{\odot}$  the radius of the Sun,  $r_{\oplus}$  the radius of the Earth, and *x* the distance between the Sun and the Earth. Derive the temperature of the Earth's surface as a function of the aforementioned parameters.

10. The coordinates of the components of Visual Binary Star  $\mu$  Sco on August 22, 2008 are given in the table below

	$\alpha$ (RA)	$\delta$ (Dec)
$\mu$ Sco 1 (primary)	20 <sup>h</sup> 17 <sup>m</sup> 38 <sup>s</sup> .90	-12° 30' 30"
$\mu$ Sco 2 (secondary)	20 <sup>h</sup> 18 <sup>m</sup> 03 <sup>s</sup> .30	-12° 32' 41"

The stars are observed using Zeiss refractor telescope at the Bosscha Observatory with aperture and focal length are 600 mm and 10 780 mm, respectively. The telescope is equipped with 765  $\times$  510 pixels CCD camera. The pixel size of the chip is 9  $\mu$ m  $\times$  9  $\mu$ m.

- a. Can both components of the binary be inside the frame? ("YES" or "NO", show it in your computation!)
- b. What is the position angle of the secondary star, with respect to the North?
- 11. Below is a picture on a 35 mm film of annular solar eclipse in Dumai, Riau, Indonesia on August 22, 1998, taken with a telescope having effective diameter 10 cm and f-ratio 15. The diameter of the Sun's disk in original picture on the film is 13.817 mm and the diameter of the Moon's disk is 13.235 mm. Determine the distances of the Sun and the Moon (expressed in km) from the Earth and the percentage of the solar disk covered by the Moon during the annular solar eclipse.

- 12. Consider a type Ia supernova, in a distant galaxy, which has a luminosity of  $5.8 \times 10^9 L_{\odot}$  at maximum light. Suppose you observe this supernova using your telescope and find that its brightness is  $1.6 \times 10^{-7}$  times the brightness of Vega. The redshift of its host galaxy is known to be z = 0.03. Calculate the distance of this galaxy (in pc) using the data of the supernova and also the Hubble time.
- 13. In the journey of a space craft, scientists make a close encounter with an object and they would like to investigate the object more carefully using their on-board telescope. For simplicity, we assume this to be a two-dimensional problem and that the position of the space craft is stationary in (0,0). The shape of the object is a disk and the boundary has the equation

$$x^2 + y^2 - 10x - 8y + 40 = 0.$$

Find the exact values of maximum and minimum of  $\tan \varphi$  where  $\varphi$  is the angle of the telescope with respect to the *x* direction during investigation from one edge to the other edge.

14. Consider a Potentially Hazardous Object (PHO) moving in a closed orbit under the influence of the Earth's gravitational force. Let u be the inverse of the distance of the object from the Earth and p be the magnitude of its linear momentum. As the object travels, the graph of u as a function of p passes through points A and B as shown in the following table. Find the mass and the total energy of the object, and express u as a function of p and sketch the shape of u curve from A to B.

	$p (\times 10^9 \text{ kg m s}^{-1})$	$u (\times 10^{-8} \mathrm{m}^{-1})$
А	0.052	5.15
В	1.94	194.17

15. Galaxy NGC 2639 is morphologically identified as an Sa galaxy with measured maximum rotational velocity  $v_{max}$  of 324 km/s. After corrections for any extinction, its apparent magnitude in *B* is  $m_B = 12.22$ . It is customary to measure a radius  $R_{25}$  (in units of kpc) at which the galaxy's surface brightness falls to 25 mag<sub>B</sub>/arcsec<sup>2</sup>. Spiral galaxies tend to follow a typical relation:

$$\log R_{25} = -0.249 M_B - 4.00,$$

where  $M_{\rm B}$  is the absolute magnitude in *B*. Apply the *B*-band Tully-Fisher relation for Sa spirals

 $M_B = -9.95 \log v_{max} + 3.15 \quad (v_{max} \text{ in km/s})$ 

to calculate the mass of NGC 2639 out to  $R_{25}$ . If colour index of the sun is  $(m_{B_{\odot}} - m_{V_{\odot}})$ = 0.64, write the mass (of NGC 2639) in units of solar mass  $\mathfrak{M}_{\odot}$  and its luminosity *B*-band in unit of  $L_{\odot}$ .

## **THEORETICAL PART 2**

#### (300 points for 3 Theoretical Part-2, 100 points for each question)

Show your method of solution step by step in the answer sheets completely as your final answer. The scratch sheet is to be used for your personal calculation and will not be marked. Partial credits will be given for answers without showing method of solution.

1. An eclipsing binary star system has a period of 30 days. The light curve in the figure below shows that the secondary star eclipses the primary star (from point A to point D) in 8 hours (measured from the time of first contact to final contact), whereas from point B to point C, the total eclipse period is 1 hour and 18 minutes. The spectral analysis yields the maximum radial velocity of the primary star to be 30 km/s and of the secondary star to be 40 km/s. If we assume that the orbits are circular and has an inclination of  $i = 90^{\circ}$ , determine the radii and the masses of both stars in unit of solar radius and solar mass.

- 2. A *UBV* photometric (*UBV* Johnson's) observation of a star gives U = 8.15, B = 8.50, and V = 8.14. Based on the spectral class, one gets the intrinsic color  $(U B)_0 = -0.45$ . If the star is known to have radius of 2.3  $R_{\odot}$ , absolute bolometric magnitude of -0.25, and bolometric correction (*BC*) of -0.15, determine:
  - a. the intrinsic magnitudes *U*, *B*, and *V* of the star (take, for the typical interstellar matters, the ratio of total to selective extinction (color excess)  $R_V = 3.2$ ),
  - b. the effective temperature of the star,
  - c. the distance to the star in pc.

Note: The relation between color excess of U - B and of B - V is E(U - B) = 0.72 E(B - V).

Let  $A_v$  be the interstellar extinction and R = 3.2, then  $A_v = 3.2 E(B-V)$ .

- 3. Measurement of the cosmic microwave background radiation (CMB) shows that its temperature is practically the same at every point in the sky to a very high degree of accuracy. Let us assume that light emitted at the moment of recombination ( $T_r \approx 3000 \text{ K}$ ,  $t_r \approx 300000 \text{ years}$ ) is only reaching us now ( $T_o \approx 3 \text{ K}$ ,  $t_o \approx 1.5 \times 10^{10} \text{ years}$ ). Scale factor *S* is defined as such  $S_0 = S(t = t_o) = 1$  and  $S_t = S(t < t_o) < 1$ . Note that the radiation dominated period was between the time when the inflation stopped ( $t = 10^{-32}$  seconds) and the time when the recombination took place, while the matter dominated period started at the recombination time. During the radiation dominated period started at the recombination time. During the radiation dominated period *s* is proportional to  $t^{1/2}$ , while during the matter dominated period *s* is proportional to  $t^{2/3}$ .
- a. Estimate the horizon distances when recombination took place. Assume that temperature T is proportional to 1/S, where S is a scale factor of the size of the Universe.
- b. Note: Horizon distance in degrees is defined as maximum separation between the two points in CMBR imprint such that the points could "see" each other at the time when the CMBR was emitted.
- c. Consider two points in CMBR imprint which are currently observed at a separation angle  $\alpha = 5^{\circ}$ . Could the two points communicate with each other using photon? (Answer with "YES" or "NO" and give the reason mathematically)
- d. Estimate the size of our Universe at the end of inflation period.
